### **[Curthoys and Halmagyi Head Impulse test: an analytical device].**

[Article in French]

Ulmer E<sup>1</sup>, Chays A.

**OBJECTIVES:** We describe hereafter a device which allows confirmation of the positive or negative test results for each of the six canals without increasing test duration.

**METHOD:** A high resolution and high light sensitivity video camera located in front of the patient's face at a distance of 80 cm is connected to a computer for automatic image analysis.

**RESULTS:** With this device, the practitioner can confirm a positive test by simple observation on the videooculocephaloscope (HIT scope) and record an image for later reference. With videooculocephalography (HIT graph), movements can be recorded for analysis to quantify the deficit of each semicircular canal.

### ***vHIT (video Impulse Test)***

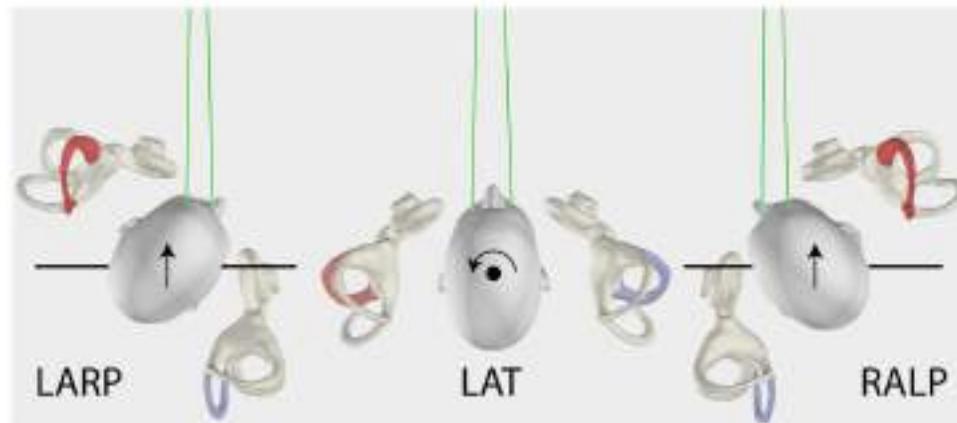

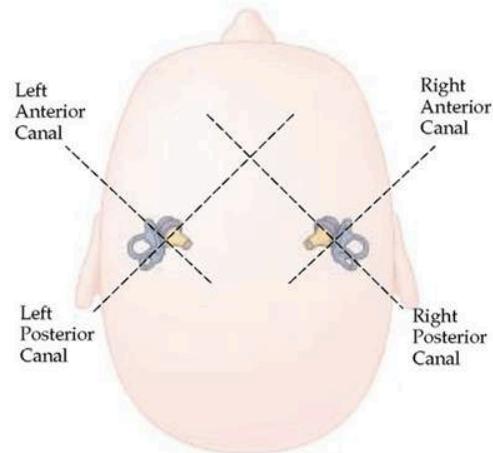

- . misurazione oggettiva del guadagno del VOR (occhi/testa =1)
- . valutazione saccadici (***covert***) che non sono visibili con il cHIT

### What does the head impulse test versus caloric dissociation reveal about vestibular dysfunction in Ménière's disease?

Leigh A. McGarvie,<sup>1</sup> Ian S. Curthoys,<sup>2</sup> Hamish G. MacDougall,<sup>2</sup> and G. Michael Halmagyi<sup>1</sup>

<sup>1</sup>Institute of Clinical Neurosciences, Royal Prince Alfred Hospital, Camperdown, NSW, Australia. <sup>2</sup>Vestibular Research Laboratory, School of Psychology, University of Sydney, NSW, Australia

sults, coupled with the fluctuating caloric results in early MD, make the **different-frequency mechanism highly unlikely to be the source of the dissociation between the caloric and vHIT in the test results in MD.** In light of these new data, we think it is time

**caloric test** in this disease is more likely to be an indication of hydroptic expansion of the horizontal membranous duct, rather than a loss of function.

Fernando Benito Gonzalez, MD; Enrique Gonzalez Sánchez, MD; Moises Arriaga, MD

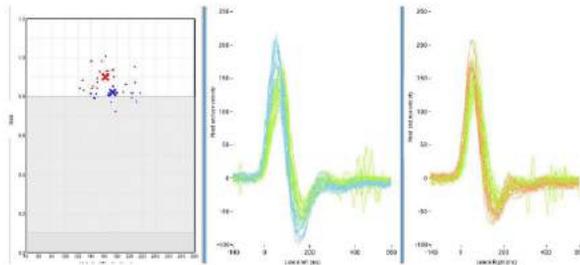

Fig. 1. Before surgery. The video head impulse test showing normal vestibular function. [Color figure can be viewed in the online issue, which is available at [www.laryngoscope.com](http://www.laryngoscope.com).]

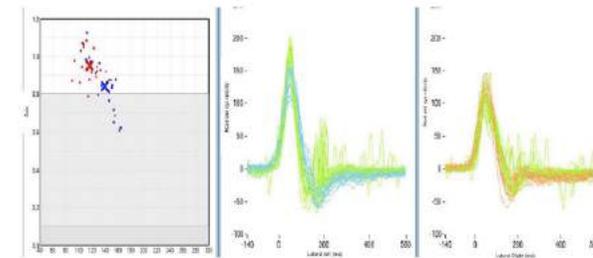

Fig. 2. After surgery (left cochlear implantation). Only saccades appear in the video head impulse test. [Color figure can be viewed in the online issue, which is available at [www.laryngoscope.com](http://www.laryngoscope.com).]

In our opinion, vHIT is an excellent procedure to test vestibular function before and after some otologic surgeries such as CI. It could offer more information about vestibular changes than other test-like calorics.

## Video Head Impulse Tests with a Remote Camera System: Normative Values of Semicircular Canal Vestibulo-Ocular Reflex Gain in Infants and Children

Sylvette R. Wiener-Vacher<sup>1,2\*</sup> and Sidney I. Wiener<sup>3</sup>

Video head impulse test is a valid, practical, and rapid diagnostic tool for detecting vestibular deficits in children as young as 3 months of age. Unlike HIT performed only by

different ages. While VOR gain is reported to remain relatively constant after the age of 16 (5, 7), there is a rapid increase until about the age of 6, following by a more moderate evolution to adult levels.

### Effect of Aging and Direction of Impulse in Video Head Impulse Test

---

Tae Hwan Kim, MD ; Min-Beom Kim, MD, PhD

Analyzing the age groups, one study reported that VOR gain reduction occurred at age 71 years in the horizontal canal, but the number of subjects was relatively small.<sup>9</sup> Our study makes confirmation of this result with the large sample size. However, unlike the horizontal canal, VOR gain in vertical canal (posterior canal and anterior canal) declined after the age of 80 years.]

## ***Video Head Impulse Test***
